# Trends in PULPWOOD PRODUCTION and CONSUMPTION in the CENTRAL STATES

Joseph J. Mendel

The timber resource of the Central States can support continued expansion of the pulpwood industry. Records for the past 6 years indicate the annual cut of pulpwood is well below the annual pulpwood growth. This is true despite the steady increase in pulpwood production in the region.

More than 1.8 million cords of pulpwood were harvested from Central States timberlands from 1955 through 1960. Pulpwood production<sup>1</sup> has increased more than 150 percent, from a low of 192,000 cords in 1955 to almost one-half million cords in 1960 (fig. 1). The 1960 harvest delivered at the mill had a value of more than 6½ million dollars. Consumption of pulpwood by Central States pulpmills during this period was approximately the same as production.

Based on current trends, it is expected that by 1965 pulpwood production in the

Central States will increase to more than 1 million cords annually.

## PRODUCTION

The total 6-year pulpwood production amounted to 1,825,000 cords, 46 percent of which was soft hardwoods<sup>2</sup>, 46 percent hard hardwoods<sup>3</sup>, and 8 percent conifers (table 1). From 1955 to 1958 both soft- and hard-hardwood production increased; production of soft hardwoods was 20 to 25 thousand cords greater than hard-hardwood annual production (fig. 2). However, in 1959 and 1960 production of hard-hardwood pulpwood exceeded that of soft hardwoods. Although production of coniferous pulpwood is low, it is increasing; in 1960 almost 40,000 cords of coniferous pulpwood were harvested.

---

<sup>1</sup>"Production" is "the harvest of pulpwood from timberlands" whereas "consumption" is "the utilization of pulpwood by mills."

<sup>2</sup>Soft hardwoods include such species as basswood, yellow-poplar, aspen, cottonwood, willow, and soft maple.

<sup>3</sup>Hard hardwoods include such species as oak, ash, hard maple, and beech.

Total	812,144	419,731	161,290	93,540	287,426	51,315	1,825,446

<sup>1/</sup> Standard cord = 4x4x8 feet of stacked bolts, 0.8 long cord or unit, 4,500 pounds of soft hardwoods, 5,000 pounds of hard hardwoods or conifers.

<sup>2/</sup> Previously published figures revised to conform with conversion factors in <sup>1/</sup>.

Throughout the 6-year period, no changes occurred in ranking of the six Central States in production (fig. 3). Ohio woodlands supplied more than 44 percent of the total 6-year pulpwood harvest. Illinois was second, accounting for 23 percent, and the other four Central States produced the remaining 33 percent.

Almost 70 percent of the hard-hardwood pulpwood produced during 1955 through 1960 came from Ohio. Illinois was the largest producer of soft hardwoods, accounting for more than 42 percent of the 6-year production, while Kentucky produced almost 90 percent of the conifers harvested for pulpwood.

FIGURE 4. — (Right) Pulpwood shipments into and out of the Central States territory, 1955-60.

## CONSUMPTION

Consumption followed much the same pattern as production, increasing 149 percent over that of 1955 (fig. 1). Pulpwood consumption from 1955 through 1960 amounted to more than 1,787,000 cords, of which 51 percent was soft hardwoods, 47 percent was hard hardwoods, and only 2 percent was conifers (table 2). The minor differences between production and consumption are due to shipments of pulpwood into and out of the Central States territory.

Ohio mills consumed 55 percent of the total pulpwood utilized during the 6-year period; Illinois mills consumed 27 percent; and mills in Indiana, Iowa, and Missouri consumed the remaining 18 percent.

During the 6-year period Central States pulpmills consumed only about 31 percent of the coniferous pulpwood produced in the region; all of the hard hardwoods were consumed within the region, while consumption of soft hardwoods exceeded production by more than 7 percent or about 63,000 cords.

## INTERREGIONAL SHIPMENTS

From 1955 through 1960 shipments of Central States pulpwood to and from neighboring states amounted to 250,000 cords. About 144,000 cords (58 percent) were "exported" and 106,000 cords (42 percent) were "imported" (table 3).

More than 91 percent of the pulpwood imported into the Central States came from Wisconsin; the remainder came from West Virginia, Michigan, Tennessee, Alabama, South Dakota, and Nebraska. About 63 percent of the imports was soft hardwoods, 30 percent was conifers, and 7 percent was hard hardwoods. Illinois mills were the principal recipients of the imports.

About 93 percent of the pulpwood exported from the Central States was conifers; almost 5 percent was hard hardwoods, and 2 percent was soft hardwoods. More than 91 percent of the pulpwood exported was harvested from Kentucky timberlands; 7 percent from Ohio, and the remaining 2 percent from Missouri and Illinois.

While the overall trend in interregional pulpwood shipments is upward, much fluctuation is evident when imports are compared with exports (fig. 4). From 1955 to 1957 exports of pulpwood were greater than imports. In 1958 and 1959, the reverse was true. But in 1960, exports again exceeded imports.

The Central States export more coniferous pulpwood than they import but they import more soft-hardwood pulpwood than they export. Imports and exports of hard-hardwood pulpwood are about equal.

## PULPWOOD CUT RELATED TO THE TIMBER RESOURCE

Approximately 22 percent or 42.5 million acres of the land in the Central States is classified as commercial forest land. The timber resources of this forest area are growing annually at the rate of 18.4 million cords<sup>1</sup>. The 1960 pulpwood cut of 491,000 cords represents approximately 3 percent of this annual growth.

In analyzing the relation between the pulpwood cut and the timber resources, the location of the resources is important. More than 60 percent of the forest land of the Central States is located in Missouri and Kentucky, states that accounted for only 18 percent of the 1960 pulpwood production. The most heavily forested areas are the least utilized for pulpwood production (figs. 5 and 6): almost two-fifths of the production was obtained from

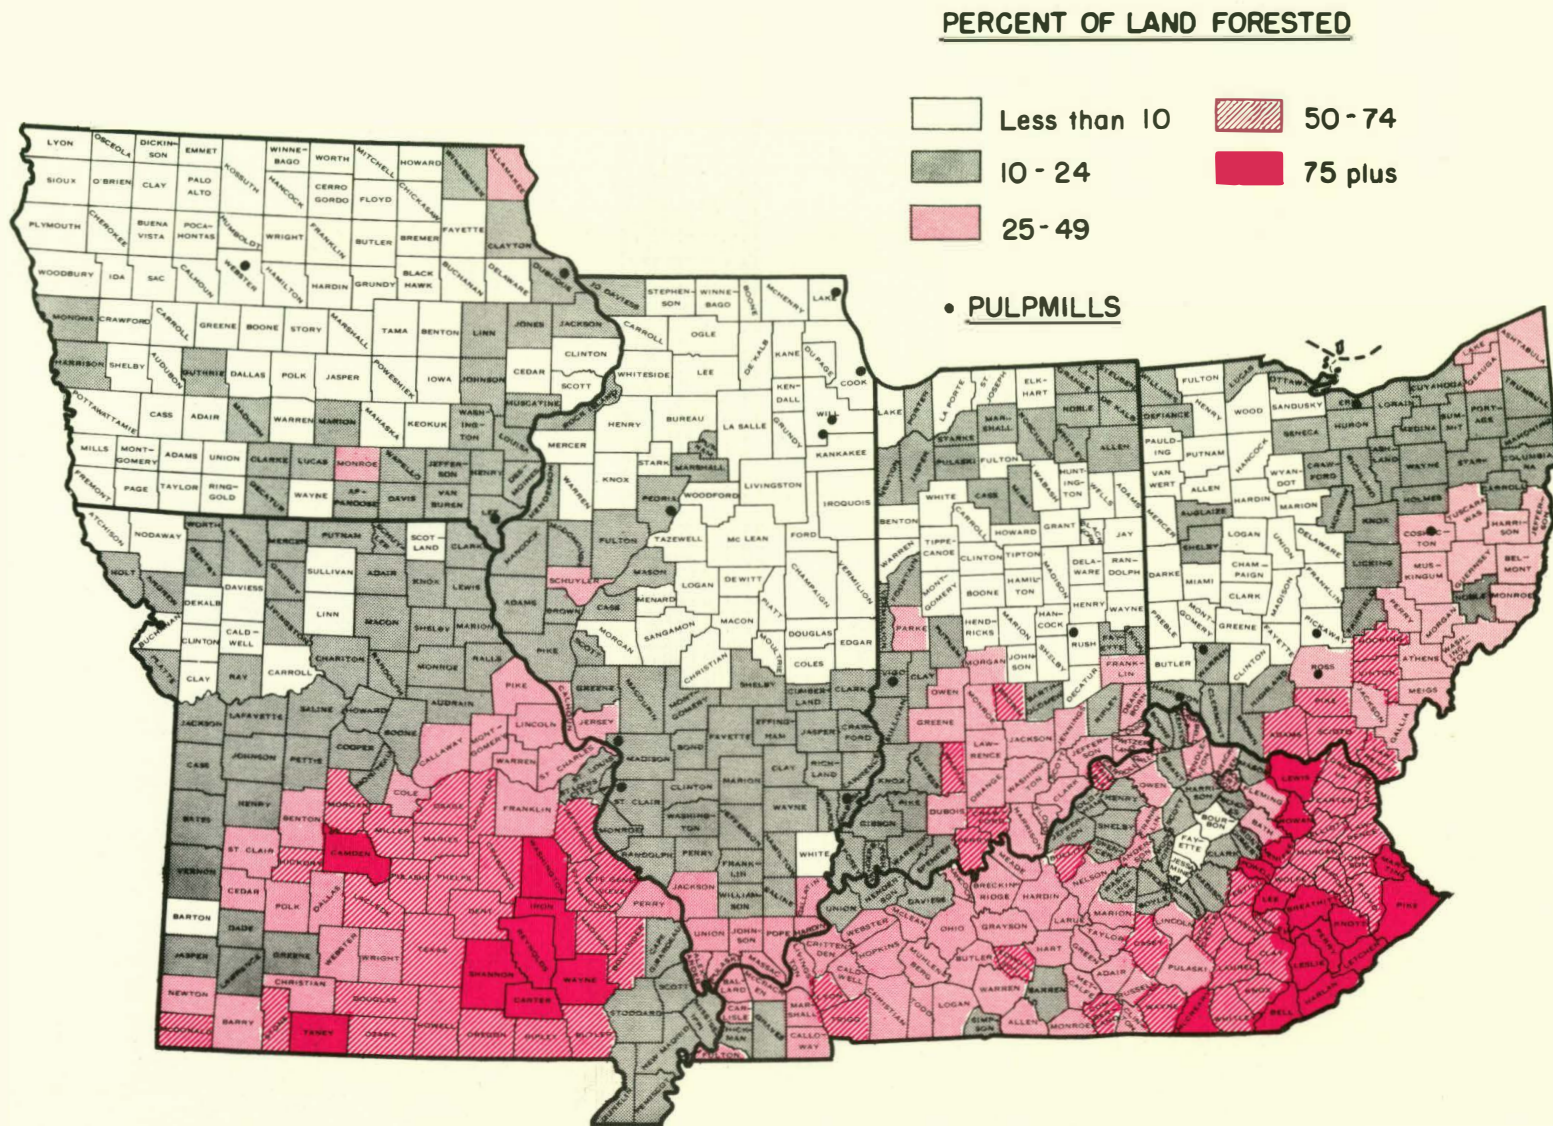

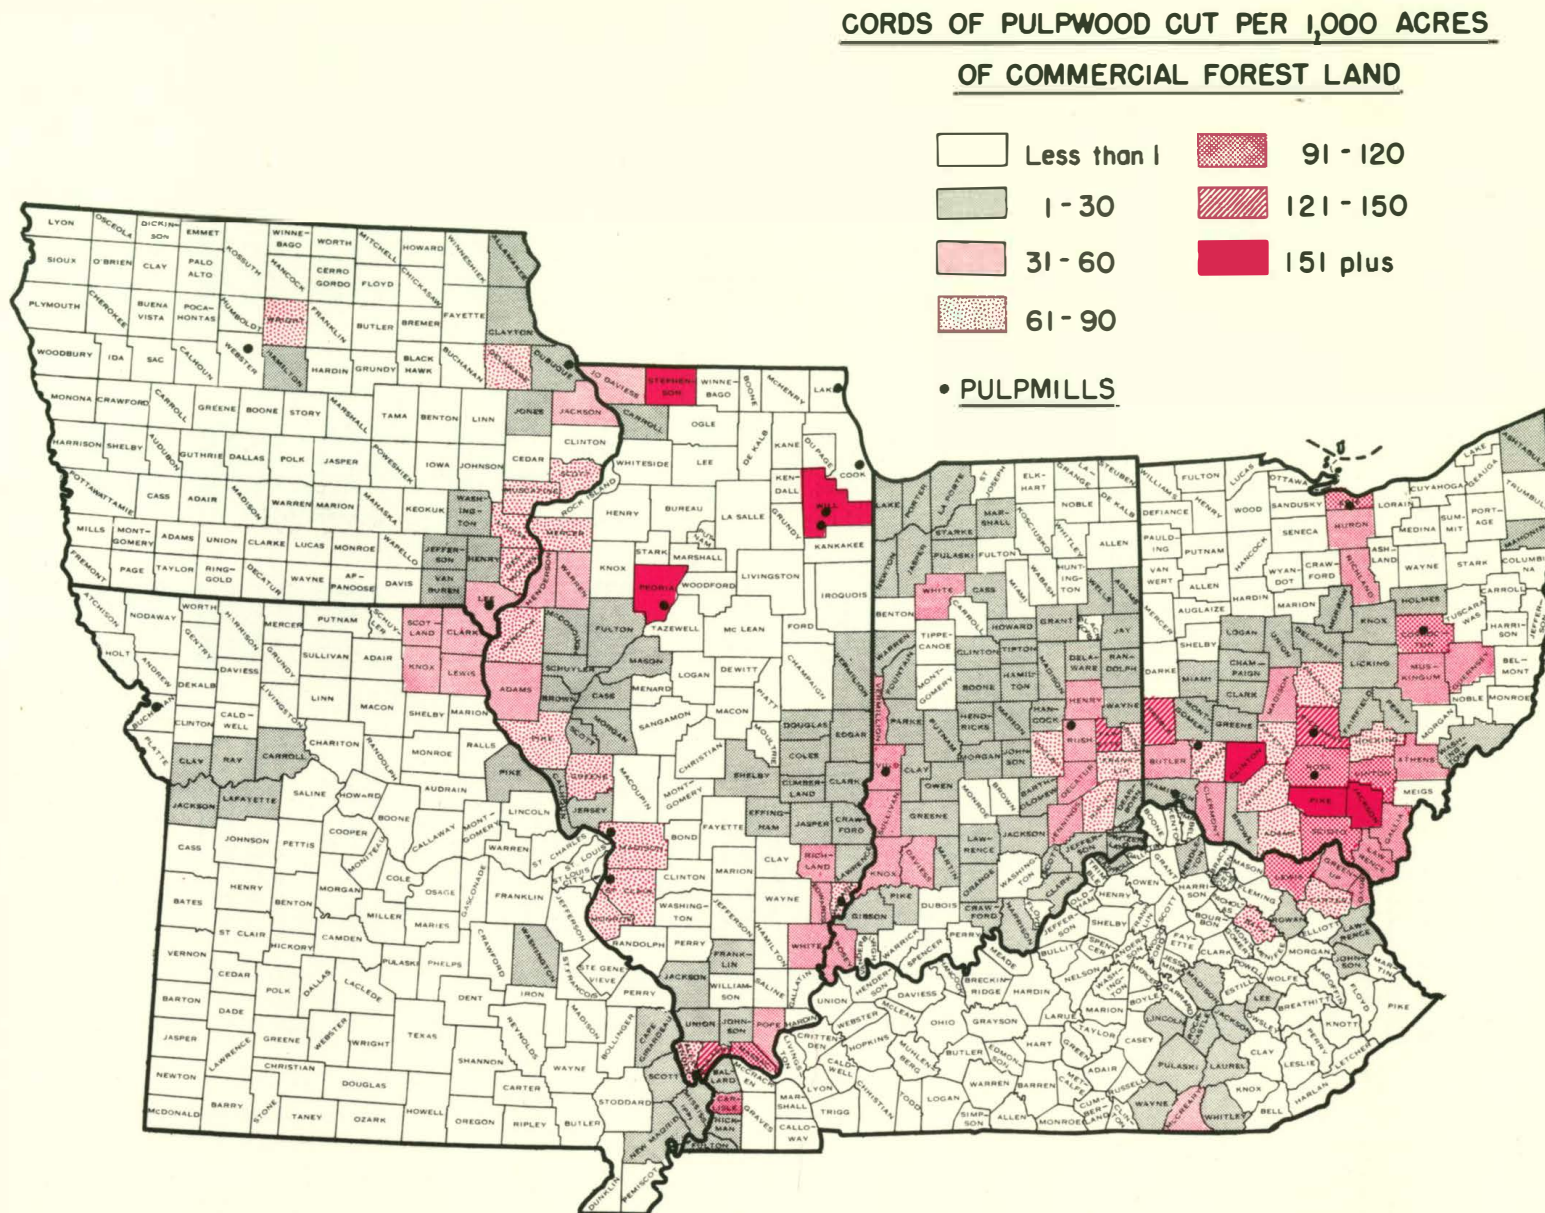

FIGURE 6. — *The 1960 pulpwood cut by county and the location of pulpmills.*

counties that were less than 25 percent forested. The remaining three-fifths was harvested from counties in which forest covers more than 25 percent of the land. Most of the three-fifths came from only 84 of these 201 heavily forested counties; 117 of the 201 counties supplied less than a cord of pulpwood per 1,000 acres of forest land.

In south-central Ohio, the area of heaviest pulpwood cutting in 1960, more than 100 cords of pulpwood were harvested per 1,000 acres of forest land. Although this cut varied by county, it averaged about 8 cubic feet per forest acre. This cut does

not approach the annual net growth, estimated to be 38 cubic feet per acre.

It is clear then that the timber resources of the Central States can easily support the present pulpwood harvest. However, the extent to which these timber resources can support an expansion of the pulpwood industry needs careful consideration. It must be recognized that other wood-using industries draw on this timber resource and that not all of the annual growth is available for pulpwood production. Also there is the need to reserve some of the annual growth to build up the growing stock both in tree size and quality.
